ABSTRACT

Background: Fibroids are the most common benign pelvic tumors affecting about 20% of women above 35 years of age. The diverse symptomatology of fibroids can be attributed to size, number and location of the tumors. The common symptoms include menorrhagia, infertility, abdominal mass and pressure effects.

Objective: To compare the efficacy of tranexamic acid and ethamsylate versus IV oxytocin infusion in reducing blood loss during abdominal myomectomy.

Patients and Methods: This study involved ninety women undergoing abdominal myomectomy for symptomatic uterine myoma divided randomly into three equal groups: Group A (Tranexamic acid and ethamsylate group) received 1 g tranexamic acid (2 ampoules of kapron 500 mg) and (1 ampoule of dicynone) IV just before skin incision, Group B (Oxytocin group) received 30 IU of oxytocin in 500 ml normal saline will be administered during myomectomy, and Group C (Saline group) received 110 ml normal saline IV just before skin incision. This study was conducted in Sayed Galal Al-Azhar University Hospital and El-Galaa Teaching Hospital during period time from December 2018 to December 2019.

Results: Using 1 g tranexamic acid and 1 ampoule of dicynone in abdominal myomectomy resulted in a significant reduction of blood loss than using 30 IU oxytocin in 500 ml normal saline immediately before the start of the surgery (509.24 ± 57.28 ml in Tranexamic acid and ethamsylate group vs. 720.13 ± 112.62 ml in oxytocin group).

Conclusion: Tranexamic acid and ethamsylate are more effective in reducing the transfusion requirement than oxytocin with more stable hematological and hemodynamic profile.

Key words: Tranexamic acid, ethamsylate, oxytocin, blood loss, abdominal myomectomy.

INTRODUCTION

Uterine myoma is the most common benign tumor in women. Various prevalence rates ranging from 20%-40% are noted in different literatures. The incidence as per the histological diagnosis is much more than the clinical diagnosis. Approximately 60% of women above 45

years of age are harboring myoma (Reis et al., 2016). Myoma is mostly asymptomatic. Size and location are the main factors that determine if a myoma leads to symptoms and problems. Important symptoms include abnormal uterine bleeding, abdominal discomfort, bloating, painful defecation, backache,

urinary frequency or retention and infertility. It is associated with impairment of health related quality of life (*Bano et al., 2017*).

There are several strategies for the treatment of fibroids, but myomectomy remains the most common and the most efficient uterus-sparing treatment (*Cohen et al., 2016*).

Myomectomy is an invasive surgical procedure and can be done abdominally, laparoscopically or by robotic method. (*Farag et al., 2018*). Substantial intraoperative blood loss and the requirements for blood transfusion remain major consideration for abdominal myomectomy (*Petermans et al., 2016*).

Cochrane Library review discussed several pharmacologic agents to reduce blood loss during myomectomy (*Saha et al., 2016*). One of the used agents is tranexamic acid. Tranexamic acid is not a uterotonic agent; TA is an anti-fibrinolytic agent better known to gynecologists for oral use as a treatment of menorrhagia, and to trauma surgeons where it has been shown to reduce blood loss (*Lecker et al., 2016*).

Several randomized clinical trials have been published which have evaluated and reviewed the efficacy of tranexamic acid in the management of abnormal gynecological hemorrhagic conditions. It is not certain how efficient tranexamic acid is in treating women with normal reproductive function and diagnosed with abnormal bleeding caused by uterine fibroids (*Bradley and Gueye, 2016*).

Ethamsylate is a hemostatic agent. It has been shown to reduce bleeding time and blood loss from wounds (*Fatah et al.,*

2018). Etamsylate limits capillary bleeding through its action on hyaluronic acid and initial studies showed a reduction in intraventricular haemorrhage. Etamsylate may also have an effect on the microcirculation, encouraging platelet aggregation and vasoconstriction and therefore haemostasis. It also inhibits the effects of the prostaglandin mediated vasodilatation and increased capillary permeability, thereby reducing oedema secondary to capillary leakage (*Ramos-Sánchez et al., 2018*).

Oxytocin is a utero-tonic drug it is the first choice drug for enhancing uterine contraction after delivery (*Vallera et al., 2017*). Oxytocin is beneficial in reduction of intra operative blood loss at cesarean section and reduces rates of postpartum hemorrhage (*Kuzume et al., 2017*).

Data from a meta-analysis of two randomized trials including 80 women showed that the infusion of oxytocin intra-operatively may be a safe and reliable method to help decrease blood loss during abdominal myomectomy compared with physiologic serum (*Atashkhoei et al., 2017*).

The aim of the current study was to compare between the effect of Tranexamic acid and Ethamsylate versus Oxytocin compared to placebo regarding their efficacy to decrease blood loss in transabdominal myomectomy.

PATIENTS AND METHODS

This prospective randomized controlled trial was conducted at Sayed Galal, Al-Azhar University Hospital and El-Galaa Teaching Hospital during the period time from December 2018 to December 2019. The study included a

sample of 90 women requiring abdominal myomectomy. All patients seeking treatment for symptomatic leiomyomas was invited to participate in the study.

Patients were divided into three equal groups: **Group 1** received 1 g tranexamic acid (2 ampoules of kapron 500 mg) and (1 ampoule of dicynone) IV just before skin incision, **Group 2** received 30 IU of oxytocin in 500 ml normal saline administered during myomectomy, and **Group 3** received 110 ml normal saline IV just before skin incision.

The study included premenopausal patients aged between 30 to 50 years old, five or less symptomatic uterine myomas, maximum diameter of the largest myoma was 6 cm, all myomas were subserous or intramural and uterine size less than 24 weeks pregnancy.

Patients with history of previous surgery, hypertension, cardiac and pulmonary diseases, patients who have bleeding disorders, anemia ($Hb < 10\text{ g \%}$), chronic endocrine or metabolic diseases such as diabetes, obesity (body mass index $> 30 \text{ kg/m}^2$) and cases that required intraoperative conversion of myomectomy to hysterectomy were excluded from the study.

All included women were subjected to the following: Preoperative: History taking including personal, present, past and obstetrics and gynecological history. Physical examination including: General examination, assessment of vital data, assessment of general condition, abdominal and pelvic examination, assessment of the uterine size and assessment of the size and location of the largest myoma if it is palpable. Laboratory

Investigations: Complete blood count. Ultrasound was performed to assess the number and location of myomas and largest myoma diameter.

Intraoperative: In all operations, the abdomen was exposed through a Pfannenstiel incision or midline vertical incision. Blood loss was estimated by measuring the amount of blood accumulated in the suction container minus used irrigation solution plus the amount of absorbed blood in used sponges. Blood lost in surgical sponges was calculated by the following formula: {postoperative wet sponge weight (g) minus preoperative dry sponge weight (g)}.

Postoperative: Follow up was every hour during the first 6 hours, and then at 12, 24 and 48 hours, and every additional 24 hours thereafter until discharge. Complete blood count was 24 hours after surgery.

The primary outcome of this study was to compare the intraoperative blood loss in the three groups. Other secondary outcomes were also compared including: the need for intraoperative blood transfusion, operative time in minutes, Difference between pre and post-operative hemoglobin and hematocrit levels and duration of hospital stay in days.

Statistical Methods:

Data were analyzed using Statistical Program for the Social Science (SPSS) version 20.0. Shapiro-Wilks test and histograms were used to checked the normality of data and all our variables were normally distributed. Quantitative data were expressed as mean \pm standard deviation (SD) and range. Qualitative data

were expressed as frequency and percentage.

The following tests were done: A one-way analysis of variance (ANOVA) when comparing between more than two means. Post Hoc test: Least Significant Difference (LSD) was used for multiple comparisons between different variables. Chi-square (χ^2) test of significance was

used in order to compare proportions between two qualitative parameters. Pearson's correlation coefficient (r) test was used for correlating data. The confidence interval was set to 95% and the margin of error accepted was set to 5%. So, the p-value was considered significant when P-value <0.05 .

RESULTS

There was no significant difference between the three groups with respect to their age, weight, height, body mass index (BMI), parity, myoma number, myoma stage, size of the largest myoma, uterine

size, initial hemoglobin and history of the previous scar. No statistically significant difference between groups according demographic data (**Table 1**).

DISCUSSION

Fibroids are the most common muscular tumors that affect women of childbearing age. They are almost always benign. It is estimated that between 20 to 50 percent of women of reproductive age have fibroids. The current treatments for uterine fibroids are many, but surgical resection is still the main treatment. Surgical removal of myomas is by abdominal myomectomy (*Yang et al., 2018*).

Till the time being there is only one study comparing the use of tranexamic acid versus oxytocin infusion in decreasing blood loss during abdominal myomectomy (*Jafari et al., 2018*). There are other studies comparing the use of tranexamic acid versus placebo during abdominal myomectomy (*Topsoee et al., 2017; Fusca et al., 2018 and Shady et al., 2018*). And the use of oxytocin versus placebo during abdominal myomectomy (*Kongnyuy and Wiysonge., 2014 and Çetin, 2019*).

In this study, there were no statistically significant differences between both groups regarding age, parity, body mass index, uterine size number of fibroids,

type of fibroid and diameter of largest fibroid. It also showed no statistically significant difference between the three groups regarding the presenting symptoms of the patients. Number of fibroids, type of fibroid and diameter of largest fibroid were not independent predictors of blood loss. The amount of intraoperative blood loss was significantly lower in those women randomized to receive 1g tranexamic acid and 1 amp ethamsylate versus 30 iu oxytocin infusion. This was possibly because tranexamic acid was acting to reduce blood loss through mechanism of fibrinolysis inhibition as it served as an antifibrinolytic. on the other hand, the concentration of oxytocin receptors existed in the non –pregnant uterus was much lower than in its pregnancy. So, we have to use oxytocin in a large dose to act on oxytocin receptors in the myometrium and fibroid tissue, which stimulates synthesis and release of contractile prostaglandins and so decreases blood supply to the arteries and fibroids. This result agreed with the study which demonstrated that the average blood loss during abdominal myomectomy was significantly higher in those women randomized to receive 30 iu

oxytocin infusion versus 400 microgram rectal misoprostol.

Jafari-Shobeiri and Colleagues (2018) showed that tranexamic acid was effective in decreasing blood loss during the myomectomy. They did not use a precise way of estimation of blood loss; the used way was counting the mops used during the operation.

In this study, we used a precise way by adding the difference in weight between the dry and soaked linen towels before and after the operation, assuming the 1 ml of blood equal 1 g of blood (*Vitello et al., 2015*).

Shady and Colleagues (2018) showed a great reduction in intraoperative and post-operative blood loss.

Only the intraoperative blood loss was measured in this study and the same was done in the study of *Jafari-Shobeiri et al. (2018)* despite the different ways of estimation of blood loss, while in study of Shady besides measuring the intraoperative blood loss, the postoperative blood loss was also measured as the amount of blood in the suction drain which was kept for 48 hrs. Postoperatively, and this was a limitation of this study.

The present study supported the study by *Fusca et al. (2018)* who found that intra-operative blood loss was significantly lower in those women randomized to receive tranexamic acid versus the placebo groups during abdominal myomectomy.

In the current study and the studies of *Topsoee et al. (2017)*, *Fusca et al. (2018)* and *Shady et al. (2018)*, tranexamic acid was administrated by different routes

(intra-venous and topical) and in variable dosages however it still decreasing Intra-operative blood loss.

Kongnyuy and Wiysonge (2014) observed that intra-operative blood loss was not significantly lower in those women randomized to receive oxytocin versus the placebo group. *Atashkhoei et al. (2017)* and *Çetin et al. (2019)*, when the dose of oxytocin was increased to 30 IU, the intra-operative blood loss was significantly lower in those women randomized to receive oxytocin versus the placebo group.

In the present study, blood transfusion was required for more patients in the oxytocin group than the tranexamic acid and ethamsylate group. However, there was no statistically significant difference between both groups.

Regarding the operative time in our study, it was significantly shorter in the tranexamic acid and ethamsylate group vs. oxytocin group as a result of the decrease in the blood loss and better surgical field, and these results agreed with the results reported by *Jafari-Shobeiri et al. (2018)*, where operative time was shorter in the tranexamic acid and ethamsylate group vs, the oxytocin group. *Fusca et al. (2018)* demonstrated that operative time was significantly shorter in the tranexamic acid and ethamsylate group compared with placebo group. *Çetin et al. (2019)* found that the duration of the operation was significantly shorter in the oxytocin group compared with placebo group.

In the present study, we compared the preoperative and postoperative hemoglobin, the preoperative and postoperative hematocrit, and we found

that the reduction in hemoglobin was significantly lower in the tranexamic acid and ethamsylate group than oxytocin group, also the reduction in hematocrit was significantly lower in the tranexamic acid and ethamsylate group than oxytocin group. These results agreed with results reported by *Jafari-Shobeiri et al.* (2018) who found that tranexamic acid group had postoperative hemoglobin values that was significantly higher than those found in oxytocin group, and found that tranexamic acid group had postoperative hematocrit values that was higher than those found in the oxytocin group.

The present study supported the study by *Fusca et al.* (2018) who found that hemoglobin reduction was lower in tranexamic acid group than control group. *Topsoee et al.* (2017) demonstrated that the drop in hemoglobin concentration and hematocrit percentage was significantly lower in the study tranexamic acid group compared with the control group.

Kongnyuy and Wiysonge, (2014) stated that the change in hemoglobin level from the day before the operation and 48h after surgery not differ significantly between the oxytocin group and the placebo group. However, in another study by *Çetin et al.* (2019), when the dose of oxytocin increased, the hemoglobin and hematocrit reduction was lower in the oxytocin group than the placebo group.

In our study, as regard the hospital length of stay, the differences between the tranexamic acid and ethamsylate group and oxytocin group were not statistically significant and these results agree with the results reported by *Jafari-Shobeiri et al.* (2018) in which length of stay in hospital in the two groups did not show a

significant difference. Investigations have reported that the most common side effects after administration of 2 gm tranexamic acid and ethamsylate are blurred vision, hypotension, diarrhea, nausea and vomiting (*Goobie, 2017*).

On the other hand, major side effects of oxytocin include hypotension, tachyarrhythmias or hyponatremia (water intoxication) (*Duffield et al., 2017*). In our study, there were no important side effects in the patients who had received tranexamic acid and ethamsylate or oxytocin. The differences between the tranexamic acid and ethamsylate group and oxytocin group were not statistically significant. This agrees with the study by *Jafari-Shobeiri et al.* (2018). This was possibly because we administered a single dose of tranexamic acid and ethamsylate or relatively low dose of oxytocin, and after surgery the patients were either still anesthetized or under the effect of an analgesic.

Tranexamic acid and ethamsylate has the advantage of the cost compared to GnRH analogs the most popular method for reducing hemorrhage in myomectomy. Although this is not their primary use, these GnRH analogs were the first treatment to be employed for myomas. However, the growth of myomas after the treatment has been noted, as well as developing the osteoporosis in long-term use; thus, GnRH analog use has been restricted only to decrease the myoma volume preoperatively and to reduce intraoperative blood loss. Another advantage over GnRH analogues is that the effect of GnRH analogues attained only after a lost time while tranexamic acid and ethamsylate can be administered

just before the operation (*Sancho et al., 2016*).

Tranexamic acid and ethamsylate have many advantages when compared to vasopressin; cost concerns are partially valid for vasopressin treatment as well as safety concerns. Some side effects have been reported to arise from the use of intraoperative vasopressin: temporary increase in blood pressure during local vasopressin injection, bleeding at injection site, and intravascular infiltration by mistake *Vezhaventhan et al., (2018)*. In addition, *Obaji et al. (2016)* reported pulmonary edema after the use of local vasopressin, and *Chilkoti et al. (2016)* reported myocardial infarction.

CONCLUSION

Tranexamic acid and ethamsylate were more effective in reducing the transfusion requirement than oxytocin with more stable hematological and hemodynamic profile.

مقارنة بين تأثير حمض الترانيكساميك مع الإيثاميسيلات وبين الأوكسيتوسين على مقدار فقدان الدم أثناء إستئصال الورم الليفي الرحمي عن طريق البطن

umar maged@yahoo.com

قسم النساء والتوليد، كلية الطب، جامعة الأزهر

E-mail: amar_maged@yahoo.com

خلفية البحث: تعتبر الأورام الليفيّة من أورام العضلات الملساء والأنسجة الضامة بالرحم. وتعد الأورام الليفيّة أكثر الأورام الحميدة شيوعاً في الحوض والتي تصيب حوالي 20% من النساء فوق عمر 35 سنة. وتعزى العيد من أمراض الأورام الليفيّة إلى حجم وعدد وموقع الأورام. وتشمل الأعراض الشائعة غزارة الطمث، العقم، كتلة في البطن وأثار الضغط.

الهدف من البحث: دراسة تأثير كلاً من حمض الترانيكساميك والإيثاميسيلات وتأثير الأوكسيتوسين على فقدان الدم أثناء عملية إستئصال الورم الليفي. وقد أجريت الدراسة في مستشفى سيد جلال الجامعي ومستشفى الجلاء التعليمي حيث تم جمع 90 مريضة مستوفيات لمعايير الدراسة.

المريضات وطرق البحث: وقد صنفت المريضات عشوائياً إلى ثلاث مجموعات متساوية:

- **المجموعة الأولى:** حصلت المريضات على جرعة 1 غرام من حمض الترانيكساميك (2 أمبولات من كابرون 500 ملخ) و1 أمبول من الإيثاميسيلات (دايسينون) وريدييا قبل شق الجلد مباشرةً.

- **المجموعة الثانية:** حصلت المريضات على 30 وحدة دولية من الأوكسيتوسين في 500 مل من محلول الملح الطبيعي خلال عملية إستئصال الورم العضلي.

- **المجموعة الثالثة:** حصلت المريضات على 110 مل من محلول ملح طبيعي وريدييا قبل شق الجلد مباشرةً.

نتائج البحث: أظهرت مجموعة الترانيكساميك والإيثاميسيلات فقدان كمية أقل من الدم أثناء العملية بالمقارنة مع مجموعة الأوكسيتوسين ومجموعة محلول الملح وكانت فروق ذات دلالة إحصائية.

الاستنتاج: يعد حمض الترانيكساميك والإيثاميسيلات أكثر تأثيراً من الأوكسيتوسين في تقليل فقدان الدم أثناء عملية استئصال الأورام الليفية من الرحم، ويقلل أيضاً الحاجة إلى نقل الدم أثناء وبعد العملية.

الكلمات الدالة: حمض الترانيكساميك، الإيثاميسيلات، فقدان الدم، استئصال الورم الليفي الرحمي عن طريق البطن.
