## ABSTRACT

**Background:** Emergence agitation (EA), although short-lived, is potentially harmful to the patient and the recovery staff. In the postoperative care unit, an agitated patient requires more nurses to control his abnormal movement and apply restraints that could result in bruises of his extremities.

**Objectives:** The objective of the study was to investigate efficacy of intraoperative magnesium sulphate on prevention of EA in adults undergoing nasal surgeries under sevoflurane anesthesia. Primary outcome of the study was to compare incidence of EA between magnesium and control group. The secondary outcome was to assess pre-operative hemodynamic parameters, sedation scores, emergence time and quality of recovery in both study groups.

**Patients and Methods:** The present study was conducted in the Al-Hussein University Hospital, following approval from the Ethics Committee of the hospital. This study included 70 adult patients of American Society of Anesthesiologists physical status I and II between 20 and 40 years of age of both sexes, non-smokers, with BMI less than or equal to 30, posted for nasal surgery under general anesthesia in which nasal packing on each side was used postoperatively. Thorough pre-anesthetic evaluation was done.

**Results:** In patients undergoing nasal surgeries, intraoperative administration of magnesium decreased the incidence and severity of postoperative agitation, ameliorated postoperative pain and shortened stay in the PACU

**Conclusion:** The intraoperative administration of magnesium sulphate in patients undergoing nasal surgeries decreased postoperative agitation, pain intensity and pethidine consumption in the early postoperative period. Intraoperative administration of saline did not decrease post operative agitation, pain intensity and pethidine consumption in the early postoperative period.

**Keywords:** Magnesium Sulphate, Emergence Agitation, Nasal Surgeries

## INTRODUCTION

Emergence agitation (EA) although short-lived is potentially harmful to the patient and the recovery staff (Berhanu, 2018).

In the postoperative care unit, an agitated patient requires more nurses to control his abnormal movement and apply restraints that could result in bruises of his extremities. In the recovery room the agitated patients might remove venous and arterial cannulas, nasal packs and

oxygen masks leading to bleeding and hypoxia. Emergence agitation is a well-documented phenomenon in children recovering from sevoflurane anesthesia (*Dahmani et al., 2010*).

The exact cause for this phenomenon remains to be undetermined. Moreover, many factors play a role in revealing emergence agitation. Several factors have been accused to increase incidence of agitations in adults; pain, hypoxia, type of operation, too rapid emergence from anesthesia, sedatives like benzodiazepines (*Suwanpasu et al., 2015*).

The incidence of emergence agitation following nasal surgery is relatively high. The exact mechanism is unknown. However, *Kim et al. (2013)* reported that the occurrence of emergence agitation could be as high as 55.4%, and the presence of nasal pack is likely to be the main trigger of agitation. *Elsery (2017)* reported an incidence of 68% following nasal surgery.

There several factors that may increase the incidence of emergence agitation; Male gender, young age, smoking, postoperative pain and premedication with atropine reported a 55% incidence of EA after nasal surgery. They demonstrated that doxapram administration, pain, and presence of a tracheal tube and or a urinary catheter appear to be the most important causes of postoperative agitation (*Rim et al., 2016*).

The phenomenon of EA became more apparent with sevoflurane and desflurane (*Locatelli et al., 2013*). Emergence agitation could be prevented or minimized if the precipitating factors are avoided.

Magnesium sulfate has been reported to decreases emergence agitation following nasal surgery. Hypotensive anesthesia is commonly used with nasal surgery to reduce bleeding and improve the surgical field, so for hypotensive anesthesia. Particular attention should be given to the high-risk group of patients such as young age, males, and smokers. Finally, adequate control of postoperative pain by multimodal analgesic approach could be of help towards a smoother recovery with a calm, alert patient.

The objective of the study was to investigate efficacy of intraoperative magnesium sulphate on prevention of EA in adults undergoing nasal surgeries under sevoflurane anesthesia.

## PATIENTS AND METHODS

This study was a prospective, double-blinded and controlled randomization study conducted in the Al-Hussein University Hospital, following approval from the Ethics Committee of the hospital.

Following patient informed consent, 70 patients of the following criteria were conducted for this study.

### Inclusion criteria:

1. Both genders.
2. Aged 20-40 years.
3. With American Society of Anesthesiologists (ASA) physical status I or II.
4. Nonsmokers.
5. BMI less than or equal to 30.
6. Elective nasal surgery under general anesthesia in which nasal packing on each side was used postoperatively.

**Exclusion criteria:**

1. Patients with history of uncontrolled hypertension.
2. Patients with ischemic or valvular heart disease.
3. Patients use MAO inhibitors or adrenergic block.
4. Cognitive impairment.
5. Patients taking antipsychotics.
6. Renal insufficiency or liver impairment.

**Duration of Study:**

November 2018 to September 2019.

Patients were randomly divided into two equal groups:

**Group (A)** received an initial intravenous loading dose of 0.3 ml/kg (30 mg/kg) of 10% solution over 10 min of magnesium sulphate. This was followed by a continuous infusion of 0.1 ml/kg (10 mg/kg/hr) for the entire duration of surgery.

**Group (B)** received an equal volume of saline 0.9%.

All patients were instructed to breathe from mouth and were observed by post-anesthesia care unit (PACU) nurse who did not participate in data collection.

All patients were intramuscularly premedicated with midazolam (0.04 mg/kg) and atropine (0.5 mg) 30 min before anesthesia induction.

All patients received the same general anesthetic technique by anesthesiologist who did not participate in data collection. General anesthesia was induced with intravenous fentanyl (1 µg/kg) and propofol (2.0 mg/kg). Tracheal intubation

was facilitated with cisatracurium (0.15 mg/kg).

Oropharyngeal packing was performed and positioning of the patients was carried out. Anesthesia was maintained with oxygen/air mixture and sevoflurane.

The operative site was infiltrated by 2% lidocaine with epinephrine (1:200,000) for bleeding and pain control. Volume-controlled ventilation will be established with an 8 ml.kg<sup>-1</sup> tidal volume and frequency to keep ETCO<sub>2</sub> in the range of 4-4.6 kPa. Standard monitoring was maintained throughout the procedure, electrocardiography, noninvasive arterial pressure, peripheral oxygen saturation, capnography, temperature.

Once the surgery was completed, the oropharyngeal pack was removed, and gentle oral suction was carried out. To antagonize the residual neuromuscular blockade at the end of the surgery, neostigmine (0.05 mg/kg) and atropine (0.01 mg/kg) were administered. Following these steps, sevoflurane was turned off in the two groups. Emergence was defined as the time interval from 'time 0' until discharge of the patient from the operating room (OR) to the post-anesthesia care unit (PACU).

**Measured parameters:**

1. Demographic data
2. Agitation level during emergence and at admission in PACU, every 5 min for the first 15 min and then every 15 min until discharged.
3. The ability to cough during emergence.
4. Other complications (desaturation SpO<sub>2</sub> ≤ 90, laryngospasm, dizziness).

5. Pain in PACU based on a 11-point numerical rating scale (0= no pain, 1-3= mild pain, 4-6=moderate pain, 7-9= sever pain, 10= worst pain).
6. Post-operative nausea and vomiting (PONV) requiring antiemetics.
7. Discharge from PACU based on modified Aldrete score (*Brattain et al., 2015*).
8. Patient satisfaction recovery after 24 hr of surgery.

#### Statistical Analysis:

Data were collected, revised, coded and entered to the Statistical Package for Social Science (IBM SPSS) version 23. The quantitative data were presented as mean, standard deviations and ranges when parametric and median with inter-

quartile range (IQR) when non parametric. Also qualitative variables were presented as number and percentages. The comparison between groups regarding qualitative data was done by using Chi-square test and/or Fisher exact test when the expected count in any cell found less than 5. The comparison between two groups regarding quantitative data and parametric distribution was done by using Independent t-test while with non-parametric distribution was done by using Mann-Whitney test.

The confidence interval was set to 95% and the margin of error accepted was set to 5%. So, the P-value was considered significant when P-value > 0.05.

## RESULTS

There was no statistically significant difference found between MgSO<sub>4</sub> and control group regarding demographic data of the studied patients except ASA classification which showed increase in cases with ASA 2 in MgSO<sub>4</sub> group than control group with p-value = 0.041. There

was no statistically significant difference found between MgSO<sub>4</sub> group and saline group regarding duration of surgery with p-value = 0.051. There was a statistically significant increase in pain score in control group than MgSO<sub>4</sub> group with p-value < 0.001 (**Table 1**).

**Table (1): Comparison between MgSO<sub>4</sub> group and control group regarding demographic data and characteristics of studied patients and duration of surgery and pain score**

## DISCUSSION

Our results showed that, in patients undergoing nasal surgeries, intraoperative administration of magnesium decreases the incidence and severity of postoperative agitation, ameliorates postoperative pain and shortens stay in the PACU.

Many inter-related postoperative events may provoke agitation, including postoperative pain and hypoxaemia, which are major confounders that may cause or result from agitation. An agitated patient can remove his oxygen mask or injure himself, resulting in more hypoxaemia and pain. In our study, none of the patients had a reduction in SpO<sub>2</sub>, excluding hypoxaemia as a confounding factor for agitation. Although pain may be the cause of agitation, it cannot be

considered the only cause of postoperative agitation for several reasons. Magnesium itself has antinociceptive properties. In a meta-analysis, including more than 1200 patients, pre-operative magnesium administration was associated with decreased postoperative morphine consumption and pain intensity at rest and on movement. In the current study, magnesium reduced pain in non-agitated patients, indicating that the mechanism of reduction of pain is independent of the reduction of agitation (*Peralta-Zamora et al., 2012*).

Reported that emergence agitation can occur even after adequate pain treatment or after procedures that are not associated with pain. Postoperative agitation is a well documented phenomenon in children recovering from sevoflurane anesthesia (*Dahmani et al., 2010*).

However, adult agitation has been recorded mainly in geriatric patients. In paediatric patients *Apan et al. (2010)* failed to demonstrate a beneficial effect of magnesium sulphate on agitation after adenotonsillectomy. In contrast, *Abdullatif et al. (2013)* showed a beneficial effect of magnesium in reducing sevoflurane agitation after the same surgical procedure. The different results between the two reports may be due to methodological issues, i.e. the former used a magnesium infusion before the end of surgery, whereas the latter used a magnesium bolus at the start and an infusion throughout surgery. This highlights the impact of dosing and timing of magnesium administration on outcome.

Postoperative agitation may occur in response to unrelated factors such as pain, medications like benzodiazepines and pethidine, certain surgical procedures, the personal characteristics of the patient, preoperative anxiety and too rapid awakening (*Suwanpasu et al., 2015*).

No single factor can explain emergence agitation. The high prevalence of postoperative agitation in our study may be due to the nature of the surgery, nasal packs, hypotensive anaesthesia or premedication with atropine. All of our patients were given premedication that included intramuscular atropine 0.5 mg 1 h before anaesthesia, but the dose of 1mg of intravenous atropine given with neostigmine to reverse residual neuromuscular block might be more likely to influence the incidence of agitation. *Yu et al. (2010)* reported that 55.4% of patients were agitated after ENT surgery. *Kim et al. (2012)* reported a 52% incidence of agitation after the same

surgery. The former used premedication of atropine 0.5 mg and midazolam 0.1mg/kg and neostigmine–atropine for reversal, whereas the latter used premedication of glycopyrrolate 0.1mg and midazolam 0.04mg/kg, and neostigmine– glycopyrrolate for reversal.

There are some evidences of a neuroprotective effect of magnesium (*Bilotta et al., 2013*).The mechanism by which magnesium reduces postoperative agitation remains to be determined. Magnesium sulphate is a non-competitive N-methyl-D-aspartate (NMDA) receptor antagonist with antinociceptive effects and also inhibits the entry of calcium ions into cells. Intravenous magnesium sulphate has been shown to suppress the increase in brain lactate concentrations and improves the electroencephalographic changes in response to cerebral ischemia (*Kang et al., 2011*).

It is possible that magnesium may have decreased agitation by protecting the brain from deleterious effects of prolonged hypotension and other contributing factors. Some types of surgery have been shown to be associated with hypomagnesaemia (*Haryalchi et al., 2013*).

Magnesium sulphate reduced the length of stay in the PACU and the dose of nitroglycerine necessary to achieve the targeted hypotensive point. This would encourage the routine use of magnesium in hypotensive anaesthesia as a sole agent or combined with other drugs.The results of the current study support the use of magnesium for postoperative agitation in adults. Strengths of the current study are that the trial is a randomised, double-blinded study with adequate power to

support the results regarding the primary outcome. Magnesium interacts with neuromuscular blocking agents by reducing acetylcholine release at the motor nerve terminal. When administered preoperatively, magnesium increases the duration of neuromuscular block produced by rocuronium (*Czarnetzki et al., 2010*).

## CONCLUSION

The intraoperative administration of magnesium sulphate in patients undergoing nasal surgeries decreased postoperative agitation, pain intensity and pethidine consumption in the early postoperative period, while intraoperative administration of saline not decrease postoperative agitation, pain intensity and pethidine consumption in the early postoperative period.

## فعالية كبريتات الماغنسيوم على التهيج المصاحب للإفاقة لدى البالغين بعد الجراحات الأنفية

ايمن حسين فهمى كحلته، وائل محمد المهدي ابراهيم، أحمد محمود شحاته السيد

قسم التخدير والرعاية المركزة، كلية الطب، جامعة الأزهر

**خلفية البحث:** التهيج المصاحب للإفاقة، على الرغم من أنه فترة قصيرة، قد تكون ضارة للمريض وطاقم التعافى . فى وحدة الرعاية بعد العملية الجراحية، يحتاج المريض إلى مزيد من الممرضات للسيطرة على حركته غير الطبيعية، وتطبيق القيود التي قد تؤدي إلى كدمات فى أطرافه.

**الهدف من البحث:** تحقيق فى فعالية كبريتات الماغنسيوم أثناء العملية على الوقاية من التهيج المصاحب للإفاقة فى البالغين الذين يخضعون لجراحات الأنف تحت التخدير سيفوفلوران. ومقارنه حدوث التهيج المصاحب للإفاقة بين الماغنسيوم ومجموعة التحكم وتقييم مؤشرات ديناميكية الدم ودرجات التهذئه، ووقت الصحو وجودة الإفاقة فى المجموعتين اللتين اقيمت عليهما الدراسة.

**المرضى وطرق البحث:** أجريت هذه الدراسة فى مستشفى الحسين الجامعي ، بعد موافقة لجنة الأخلاقيات بالمستشفى وشملت هذه الدراسة 70 مريضاً بالغاً حسب الجمعية الأمريكية لأطباء التخدير الوضع البدني الأول والثاني بين 20 و 40 عاماً من كلا الجنسين ، من غير المدخنين ، مع مؤشر كتلة الجسم أقل من أو يساوي 30 ، لجراحة الأنف تحت التخدير وتقييم شامل للتخدير.

**النتائج:** يقلل تناول الماغنسيوم أثناء العملية فى المرضى الذين يخضعون لجراحات الأنف من حدوث وشدة التهيج المصاحب للإفاقة بعد العملية الجراحية ، ويخفف من آلام ما بعد الجراحة، ويقصر البقاء فى وحدة الرعاية بعد العملية الجراحية.

**الإستنتاج:** عقار كبريتات الماغنسيوم فعال فى تقليل التهيج المصاحب للإفاقة فى المرضى الذين يخضعون لجراحات الأنف وقوة الألم واستهلاك البيثيديين فى وقت مبكر فى فترة ما بعد الجراحة، بينما إستخدام المحلول الملحي غير فعال فى تقليل التهيج المصاحب للإفاقة فى المرضى الذين يخضعون لجراحات الأنف وقوة الألم واستهلاك البيثيديين فى وقت مبكر فى فترة ما بعد الجراحة.
